Abstract – Cancer has become a major fatal disease in China. The relatively lower early detection rates for multiple cancer types have been one of the main reasons for a relatively lower cancer curative rate in China compared with the developed countries. To investigate trends in the early cancer detection rate over the past 5 years in a major city of China, 45,260 patients with newly diagnosed cancers of the nasopharynx, lung, thyroid, colorectum, liver, breast, uterine cervix, stomach, esophagus, blood, and kidney from 2016 to 2020 at Sun Yat-sen University Cancer Center were evaluated. The early detection rate (stage I disease) for all cancer types in combination significantly increased from 14.4 to 23.07%. Among the studied cancer types, a significant increase in stage I cancers was proportionally seen in cancers of the lung, thyroid, colorectum, and uterine cervix. While for cancers of the liver and stomach, a significant proportional increment was only observed when combining stage I and stage II diseases. No significant alteration in early cancer detection of the nasopharynx, breast, esophagus, blood, or kidney was observed. Three limitations of this present study include relatively small cohorts of cancer patients, relatively short observation periods, and limited sample representativeness. Further efforts are anticipated to validate our findings with larger patient cohorts from different parts of China and enhance early cancer detection rates by promoting public awareness, applying better health care policies, and improving insurance coverage and medical resources.

Key words: Cancer incidence rate, Early detection, Lung cancer, Thyroid cancer, Nasopharyngeal cancer, Colorectal cancer, Gastric cancer, Cervical cancer, Renal cancer.

Background

Cancer has become a major fatal disease in China, with over 3.9 million yearly new cases and over 2.3 million cancer deaths [1]. One of the key factors responsible for the high mortality rate of cancer patients in China is a relatively low early detection rate [2].

Different cancers have different alarm symptoms. For those with apparent early alarm symptoms, the proportion of stage I disease is expected to be high; and this is the rationale for promoting public awareness. With improvements in public awareness, insurance coverage, and the healthcare system, early cancer detection rates are expected to improve in most of China [3–5]. However, the available data for analyzing early detection rates in China is limited, not to mention the dynamic alteration of early detection rates with the passage of time. In this present study, we retrieved data of newly diagnosed cancer patients

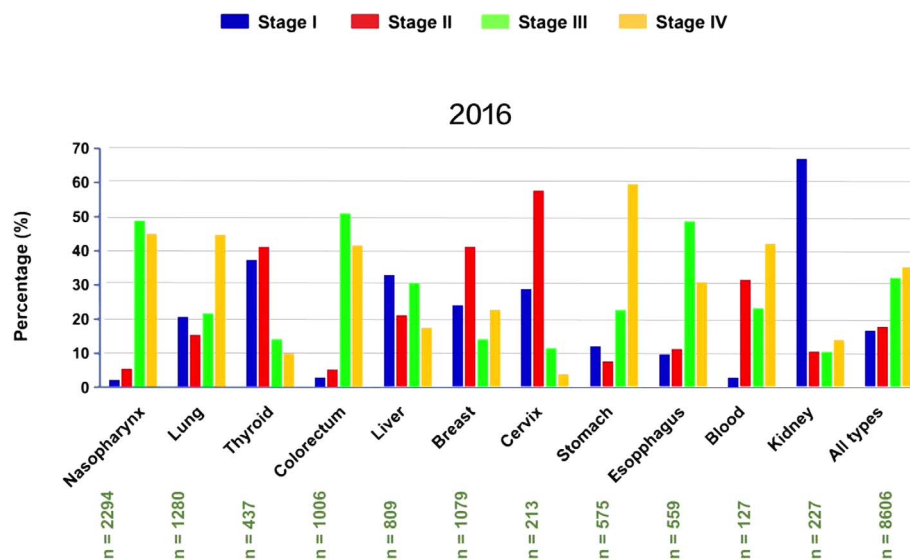

from a single institution in a major Chinese city to generate some clues to better understand the increase in early cancer detection rates in China, followed by a discussion on the possible underlying and influencing factors.

Methods and materials

Patient cohorts

Patients with newly diagnosed cancers of the nasopharynx, lung, thyroid, colorectum, liver, breast, uterine cervix, stomach, esophagus, blood, and kidney from 2016 to 2020 at Sun Yat-sen University Cancer Center were analyzed. These patients had sufficient clinicopathological data for staging analysis. The total analyzed patient numbers were 8,601 in 2016, 8,185 in 2017, 8,565 in 2018, 9,573 in 2019, and 10,336 in

Increments in early detection rates for lung, thyroid, colorectum, cervix, liver, and stomach cancer resulted in a steady increase in early detection rates for all types of cancer when combined together. <https://vcm.edpsciences.org/10.1051/vcm/2022001#V1>

2020. This present study was approved by the Institutional Review Board of Sun Yat-sen University Cancer Center with the approval number: ZDMB-2020-001-01.

The staging systems

The 8th edition American Joint Committee on Cancer (AJCC) TNM staging systems were used for nasopharyngeal cancer, breast cancer, gastric cancer, cervical cancer, thyroid cancer, colorectal cancer, hepatocellular cancer, and renal cancer. The 8th edition of the Union for International Cancer Control (UICC) staging systems were used for lung cancer and esophageal cancer. Blood cancers in this present study included lymphoma (staged using the Ann Arbor MIPI, and LUGANO systems), leukemia (staged using the Rai system), and multiple myeloma (staged using the Revised International Staging (R-ISS) system).

Statistical analyses

The Cochran–Armitage trend test was applied to evaluate the percentage increments in early-stage diseases. A *P* value less than 0.05 was considered significant.

Results

General tendency

Video 1 shows the proportional alterations of four clinical stages for different cancer types within the studied 5-year period. Generally speaking, the early detection rate for all cancer types calculated by stage I tumors alone significantly increased from 14.4 to 23.07% within the 5 years (Table 1).

Increase in early cancer detection rates of the lung, thyroid, colorectum, cervix, liver, and stomach

Table 1 shows a significant increase in the proportion of stage I cancers of the lung, thyroid, colorectum, and uterine cervix. While in the liver and stomach cancers, the significant proportional increase was only observed by combining stage I and stage II cancers.

No significant changes in early cancer detection of the nasopharynx, breast, esophagus, blood, or kidney

Even though nasopharyngeal carcinoma (NPC) is a common malignancy in southern China [6], its early detection rate is extremely low (1.6–2.5% of stage I disease). Notably, the relatively high early detection rates in kidney cancer (57.7–66.7% for stage I disease) were not significantly altered within the studied time period, neither were early cancer detection rates for breast (18.2–24.3%), esophagus (9.4–11.7%), or blood (0–7.3%).

Discussion

The benefits of promoting early cancer detection and early cancer treatment include saving more lives, reducing direct medical costs, reducing the disability rate, reducing personal psychological stress, and preserving patients' vitality. Two major factors influencing China's early cancer detection rate are medical insurance coverage and public awareness of early cancer detection [7, 8]. However, it is also believed that limited medical resources for routine medical check-ups among the adult population in China have also prevented early detection for most cancer types.

Lung cancer has been the leading cause of cancer-related deaths in many countries for many years, with its incidence

Table 1. Increase in early detection rates presented by the percentages of stage I or stages I + II diseases.

Cancer Type	Stage included	Percentage in indicated year					Cochran–Armitage (Z) P Value
		2016	2017	2018	2019	2020	
Lung	Stage I	16.88	20.24	25.29	31.94	36.17	<0.0001
Thyroid	Stage I	29.98	37.63	45.95	41.29	56.87	<0.0001
Colorectum	Stage I	4.47	2.79	6.74	5.92	6.59	0.0031
Cervix	Stage I	10.33	30.26	33.54	23	37.94	<0.0001
Liver	Stages I and II	54.51	52.51	60.37	58.55	61.04	0.0007
Stomach	Stages I and II	16.35	19.23	16.97	27.23	29.48	<0.0001
All types	Stage I	14.4	16.48	20.27	18.49	23.07	<0.0001

highly related to smoking practice [9]. The incidence of lung cancer in the male population of China has been stable at about 47/100,000 between the years 2000 and 2015, while it has increased in females from 20/100,000 to 25/100,000 for the time period between 2010 and 2015 [1]. Although this deadly disease had a very high mortality rate before the emerging and wide application of targeted drug therapy, a slight reduction in lung cancer mortality in both genders between 2000 and 2015 has been observed in China [1]. This can be explained by increased public awareness and an increase in low-dose computed tomography (CT) scanning among cigarette smokers [10].

Despite increases in lung cancer incidence in both genders in China over the past several decades [11, 12], the early detection rate of lung cancer has also been improved in several institutions [13, 14]. It is expected that in addition to using low-dose CT for screening, the application of other novel self-sampling technologies might be able to further improve the lung cancer early detection rate [2].

Thyroid cancer is the most common head-and-neck malignancy globally and accounts for 1–2% of all malignancies worldwide [15]. The rapid increase in the incidence of thyroid cancer has been reported by other researchers [16, 17]. In 2015, approximately 200,700 new thyroid cancer cases were diagnosed in China, accounting for 5.11% of all new cancer cases, with the incidence rate ranked 7th among all cancers [17]. The major histological types of thyroid cancer include papillary thyroid carcinoma (PTC), follicular thyroid carcinoma (FTC), medullary thyroid carcinoma (MTC), and poorly differentiated thyroid cancer.

Both papillary and follicular cancers derive from thyroid follicular epithelial cells, and they are grouped as differentiated thyroid cancer (DTC), accounting for 95% of cases. With total thyroidectomy and radioiodine treatment, DTC is an indolent and curable disease in most patients, whereas the curative rate of MTC is lower and depends on early diagnosis. The histologic type of thyroid cancer which has contributed to a rapid increase in its worldwide incidence is PTC [18]. This rapid increase in thyroid cancer has aroused widespread public concern. Environmental risk factors, including a deficit or excess of iodine intake [19], medical radiation [20], and nutrition-related factors [21], have also been proposed to be partially responsible for this increase. The application of advanced diagnostic techniques, especially ultrasonography, computed tomography, and magnetic resonance imaging, have been

proposed as the main reason for the increase in early detection rates [22–24].

The greatest potential for reducing cancer-related deaths is through increasing early diagnosis rates in the short term. This understanding has led to efforts to detect symptomatic cancers earlier and, eventually, to detect occult cancers in asymptomatic persons through screening. From the mid-20th century, accumulating evidence has supported the introduction of screening for cancers of the cervix, breast, colorectum, prostate, and lung. Screening for cancer using radiographic imaging has been available for decades, and multiple clinical studies have demonstrated its efficacy in specific instances. The three cancers with the best consensus for the greatest benefits from early cancer detection using imaging include breast cancer, colorectal cancer, and lung cancer. Blood-based tests often called liquid biopsies, which detect circulating tumor-derived factors such as circulating tumor cells (CTCs) [25] and circulating tumor DNA (ctDNA) [26], have shown potential usage in early diagnosis. ctDNA testing could also be used synergistically with other multi-omic biomarkers to enhance early detection. For instance, assays that incorporate early detection proteins (i.e., CA-125), epigenetic markers, circulating tumor RNA, nucleosomes, exosomes, and associated immune markers have been explored [27]. However, the sensitivity of these tests to detect small tumors is still too low for routine clinical usage. Many obstacles must be overcome before a blood-based screening test, incorporating either CTCs or ctDNA, could become a valuable asset for early cancer diagnosis.

There are several other barriers preventing early cancer detection when screening high-risk populations. Individuals with lower economic incomes [28], lower educational achievements [29], and those without insurance [28, 30] are less likely to join screening programs. With improvements in health care policies and insurance coverage, it is expected that more high-risk populations might be willing to join cancer screening initiatives [31–33].

Three limitations of this present study include relatively small cohorts of cancer patients, relatively short observation periods, and limited sample representativeness as all data came from a single institution. These limitations might generate biases in our findings. Therefore, our findings should be validated by further studies with larger cohorts from different parts of China with longer observation periods.

In conclusion, despite the limited representativeness, increments of early detection rates of multiple cancer types have

been observed over the past 5 years at a single institution in South China. More efforts are expected for further enhancing early cancer detection rates by improvements in public awareness, health care policy, insurance coverage, and medical resources.
